

RADIOLOGY REPORT - MRI RIGHT KNEE WITHOUT CONTRAST

CLINICAL HISTORY: 24-year-old recreational soccer player with acute right knee injury sustained during a pivoting maneuver three days ago. Positive Lachman and pivot-shift tests on exam.

FINDINGS: Complete full-thickness tear of the anterior cruciate ligament (ACL) with associated bone marrow edema at the lateral femoral condyle and posterior lateral tibial plateau. Menisci are intact. No evidence of collateral ligament injury or chondral defect.

IMPRESSION: Complete ACL rupture, right knee. Findings are consistent with the clinical diagnosis of ACL reconstruction candidacy. Recommend orthopedic surgery referral for operative planning.
